Policy

Commercial Members: Managed Care (HMO and POS), PPO, and Indemnity
Medicare HMO BlueSM and Medicare PPO BlueSM Members

Genetic testing to determine cytochrome p450 (CYP2C19) genetic polymorphisms for the purpose of managing the treatment of H. pylori infection is INVESTIGATIONAL.

Prior Authorization Information

Commercial Members: Managed Care (HMO and POS)
This is NOT a covered service.

Commercial Members: PPO, and Indemnity
This is NOT a covered service.

Medicare Members: HMO BlueSM
This is NOT a covered service.

Medicare Members: PPO BlueSM
This is NOT a covered service.

CPT Codes / HCPCS Codes / ICD-9 Codes
The following codes are included below for informational purposes. Inclusion or exclusion of a code does not constitute or imply member coverage or provider reimbursement. Please refer to the member’s contract benefits in effect at the time of service to determine coverage or non-coverage as it applies to an individual member. A draft of future ICD-10 Coding related to this document, as it might look today, is included below for your reference.
Providers should report all services using the most up-to-date industry-standard procedure, revenue, and diagnosis codes, including modifiers where applicable.

### CPT Codes

</table>

**Description**

Helicobacter pylori (H. pylori) is a bacterium associated with a range of gastrointestinal disorders, such as peptic ulcer disease, chronic gastritis, and gastric malignancy. Eradication of H. pylori has been proven beneficial for a number of indications.

Currently, multiple regimens are available for treating H. pylori infection. These include proton pump inhibitors (PPIs) to suppress acid production in combination with antibiotic treatment.

Differences in PPI metabolism lead to variability in gastric acid suppression, with associated variability in gastric pH, and potential impact on the efficacy of H. pylori treatment. Observational research suggests that patients who are extensive metabolizers of PPIs have lower eradication rates following standard treatment for H. pylori, compared with poor metabolizers.

Improved eradication rates for H. pylori could lead to improved health outcomes by reducing the need for retreatment following treatment failure, reducing recurrences of H. pylori-associated disorders, and reducing the morbidity and mortality associated with disease recurrence.

Examples of commercially available genetic tests for H.pylori treatment include the AmpliChip Cytochrome P450® Genotyping test from Roche. All genetic tests for H.pylori treatment are considered investigational regardless of the commercial name, the manufacturer or FDA approval status.

**Summary**

The scientific evidence does not permit conclusions on whether the use of a pharmacogenomics-based treatment regimen for H. pylori improves eradication rates. In general, eradication rates of H. pylori vary by CYP2C19 status. In the single randomized controlled trial comparing a pharmacogenomics-based treatment regimen with a standard regimen, eradication rates after first-line treatment were higher for the pharmacogenomics group compared with the standard treatment group. However, because of numerous variations in treatment protocol within the pharmacogenomics group, it is not possible to determine whether the improvement resulted from the tailored PPI dosages according to CYP2C19 genetic status or due to other variations in the treatment protocol unrelated to CYP2C19 status. The use of a PPI that is less susceptible to CYP2C19 status, such as rabeprazole, has been associated with higher eradication rates compared to other PPIs. Additional trials are needed, including alternative treatment regimens, before conclusions can be made on whether a pharmacogenomics-based treatment regimen improves H. pylori eradication rates compared to a standard treatment regimen. Therefore, the use of genetic testing for Helicobacter pylori treatment is considered investigational.
